Dear Business Partner!

April 2013 a farmer in Austria showed interest in our FRONT-TURBO seeder and fertilizer spreader. Quickly we agreed with this deal and he informed about his special idea.

fertilization

Interested we visited this customer 12th July to experience something about the results.

The parcels left hand side shows a surprising development compared to the right side parcel.

Even with fertilizer use of 50% on left hand parcel compared to 100% on right hand side.

12.07.2013

11.08.2013

Cultivation with STRIP CAT 50% Mineral fertilizer placed at 15-20mm deep behind the tine.

Cultivation with plough power harrow and 100% fertilizer even spreading.

Last year customer experienced very weak culture and dramatic erosion by heavy rain.

21.09.2013

After last year Maize harvest customer seed rye corn for cover crop. Early may 30-40 cm high crop was pressed down by a roller before STRIP TILL cultivation.

11.08.13

11.08.13 Erosion has removed soil and fertilizer

Due to placing the fertilizer behind the tine into deeper soil section the “N” in gased condition developend full activity.

The reason to reduce fertilizer at start was, to spread the second part during row cultivation when the crop is about 20-30cm high.

This investment could be saved and crop showes perfect result.

Also chemicals could be saved a lot, as weed between rows had no fertilizer and slowed down development.
A strong Maize culture also stops activity and damage of insects. Much higher resistance further illness.

Finally this combination offers great profit for farming.
